Universal Workflow Report - Predicting Student Pass/Fail

Introduction

This project applies the Deep Learning with Python (DLWP 4.5 universal workflow, part 1) to the student Alcohol Consumption dataset from Kaggle. The dataset contains information about 395 school students. The aim is to predict whether a student will pass (G3 ≥ 10) or fail (G3 < 10) based on demographic, social, and academic attributes.
This project was constrained to Sequential Dense and Dropout layers only; no other layers were used. In this notebook, baseline, neural network models, hyperparameter tuning, regularisation, and cross-validation experiments were done.

Import Resources

In [1]:
```
import warnings
warnings.filterwarnings('ignore')
```

In [2]:
```
# core libraries
import numpy as np
import pandas as pd

# Preprocessing and evaluation
from sklearn.model_selection import train_test_split
from sklearn.metrics import classification_report, confusion_matrix
from sklearn.preprocessing import StandardScaler

# Deep learning / keras for neural network models
import tensorflow as tf
from tensorflow.keras import Sequential, layers

# plotting
import matplotlib.pyplot as plt
import seaborn as sns
```

Load the Dataset

The dataset contains both categorical (eg, school, sex, address, family support, parental job) and numerical features (eg, age, absence, study time, previous grades). Since neural networks expect numeric inputs, categorical variables require variable conversion into numeric form. Categorical variables were transformed using one-hot encoding. This creates binary indicator variables(0/1) for each category, ensuring the model can learn from categorical differences without introducing artificial order.

In [3]:
```
# load the dataset
data = pd.read_csv("C:/Users/ALISHA/Downloads/archive (5)/student-mat.csv")
```

In [4]:
```
# preview first few rows
print(data.head())
print(data.shape)
print(data.info())
```

```

Target Variable

The student Alcohol dataset has a column called G3, which is the final grade of each student(integers). 10 or above equals to a pass and below 10 equals to a fail. G3 is used for defining a binary classification = pass/fail The dataset contains 395 students, of whom 67% passed and 33% failed. This imbalance motivated the use of precision, recall, F1-score, and accuracy.

In [5]:
```
# deciding the prediction target
# creating binary target 1 = pass G3 more than equal 10), 0 = fail (G3 less than 10
data["pass"] = (data["G3"] >= 10).astype(int)

# features and target
X = data.drop(columns=["G3", "pass"])
y = data["pass"]
```

In [6]:
```
print(data['pass'].value_counts())
```

```
pass
1    265
0    130
Name: count, dtype: int64
```

Preprocessing

Categorical variables were one-hot encoded, numerical features were standardized, and the dataset was split into training, testing using an 80/20 stratified split. 80% training and 20% testing using train_test_spilt with stratify=y. Stratification preserved the pass/fail ratio across both sets, ensuring that the test set was a representation of the full dataset.

In [7]:
```
# one-hot encode categorical variables
X = pd.get_dummies(X, drop_first=True)
```

In [8]:
```
# train/test split with stratfication
from sklearn.model_selection import train_test_split

X_train, X_test, y_train, y_test = train_test_split(X, y, test_size = 0.2, random_s
```

In [9]:
```
# standardise features(fit on train)
from sklearn.preprocessing import StandardScaler

scaler = StandardScaler()
X_train = scaler.fit_transform(X_train)
X_test = scaler.transform(X_test)
```

Baselines

Two baseline models were trained for comparison: Dummy Classifier(majority class rule): Always predicts “pass”. Achieved 67% accuracy. Logistic Regression: A linear model. Achieved 78% accuracy.

Dummy classifier (Naive Baseline): The dummy classifier(majority class rule): Always predicts “pass”. Achieved 67% accuracy. This provides a naive baseline and any useful model must outperform this.

In [14]:
```
# dummy classifier: always predict majority class
from sklearn.dummy import DummyClassifier
from sklearn.metrics import accuracy_score, classification_report, confusion_matrix

dummy = DummyClassifier(strategy="most_frequent")
dummy.fit(X_train, y_train)
y_dummy = dummy.predict(X_test)

print("Dummy Baseline Accuracy:", accuracy_score(y_test, y_dummy))
print(confusion_matrix(y_test, y_dummy))
print(classification_report(y_test, y_dummy))
```

```

```

Baseline Neural Network

Building the first deep learning model using the DLWP Part 1 workflow. The architecture consists of two hidden layers, 64 -> 32 units with ReLU activations and dropout 0.3 for regularisation, followed by a single sigmoid output unit for binary classification.
The model is compiled with the Adam optimizer and binary cross-entropy loss, and trained for up to 50 epochs with a batch size of 16. A validation split of 20% is used to monitor performance and detect overfitting. During training, accuracy steadily increases while validation accuracy stabilizes around 82 to 84%, suggesting that the network has learned meaningful patterns but may be slightly overfitting compared to training accuracy.

In [10]:
```
from tensorflow.keras import Sequential, layers

model = Sequential([
    layers.Dense(64, activation="relu", input_shape=(X_train.shape[1],)),
    layers.Dropout(0.3),
    layers.Dense(32, activation="relu"),
    layers.Dropout(0.3),
    layers.Dense(1, activation="sigmoid")
])

# compile model
model.compile(
    optimizer="adam",
    loss="binary_crossentropy",
    metrics=["accuracy"]
)

# training the model
history = model.fit(
    X_train, y_train,
    validation_split=0.2,     # reserve 20% training data for validation
    epochs=50,                # train for up to 50 epochs
    batch_size=16,            # use mini-batches of 1
    # verbose=1               # training process
)
```

Model Evaluation: The baseline neural network is evaluated on the held-out test set. The model achieves an accuracy of 82%, showing a substantial improvement over the Dummy Classifier (67%) and Logistic Regression(78%).

The confusion matrix and classification report reveal that the model performs better at predicting students who pass(recall = 0.88) compared to those who fail (recall = 0.77). This aligns with the class imbalance in the dataset (67% pass vs 33% fail).

Overall, the evaluation confirms that the neural network generalizes reasonably well, but it is slightly biased towards predicting passes

In [11]:
```
#evaluate the trained model on test set
test_loss, test_acc = model.evaluate(X_test, y_test, verbose=0)
print(f"Test Accuracy: {test_acc:.2f}")
```

```python
# Predictions
y_pred = (model.predict(X_test) > 0.5).astype("int32")

# confussion matrix and classification report
from sklearn.metrics import classification_report, confusion_matrix
print(confusion_matrix(y_test, y_pred))
print(classification_report(y_test, y_pred))
```

```

```

Training Curves - Accuracy: The training and validation accuracy curves show that the model quickly learns in the first 10 epochs, reaching above 80% accuracy. Training accuracy continues to rise towards nearly 100%, while validation accuracy stabilizes around 83-85%.

This indicates that the model generalises reasonably well but exhibits signs of overfitting, as the gap between training and validation accuracy widens over time.

In [12]:
```python
# plot training vs validation accuracy
plt.plot(history.history['accuracy'], label='Tain acc')
plt.plot(history.history['val_accuracy'], label='Val acc')
plt.xlabel('Epochs')
plt.ylabel('Accuracy')
plt.legend()
plt.show()
```

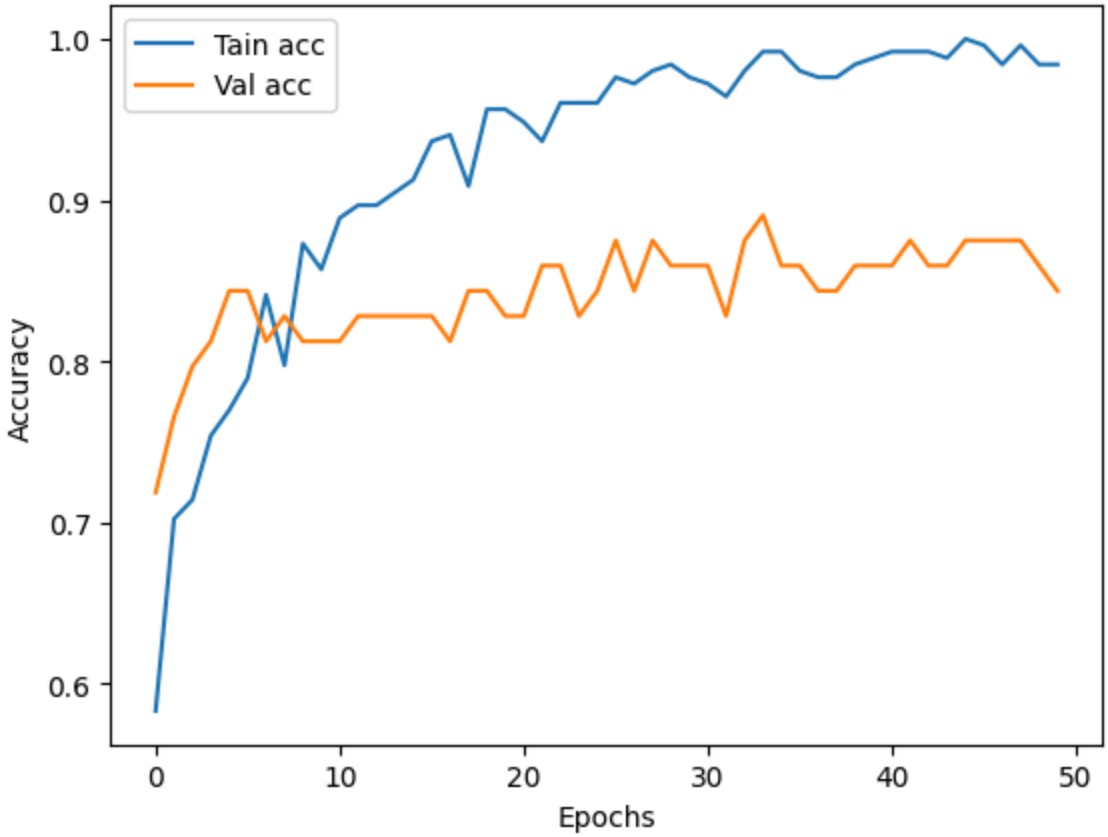

Figure 1: Training vs Validation Accuracy over 50 epochs

Training Curves - Loss

The training and validation loss curves confirm this trend. Training loss steadily decreases, while validation loss plateaus and fluctuates after 10 epochs. This pattern further supports the observation of mild overfitting: the model fits the training data extremely well but struggles to improve beyond a certain point on the validation set.

In [13]:
```
# plot training vs validation loss
plt.plot(history.history['loss'], label='Train Loss')
plt.plot(history.history['val_loss'], label='Val Loss')
plt.xlabel('Epochs')
plt.ylabel('Loss')
plt.legend()
plt.show()
```

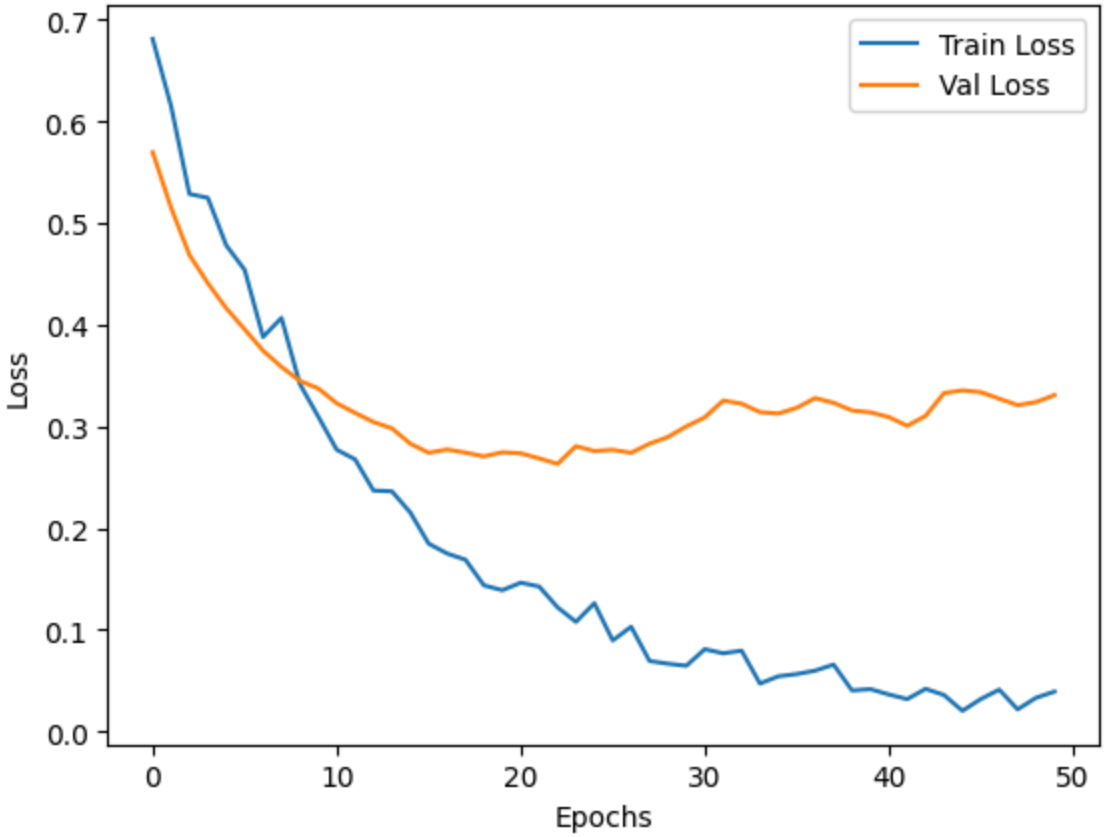

Figure 2: Training vs Validation Loss over 50 epochs

Regularisation with L2 Penalty: In addition to dropout, we apply L2 weight regularisation to the Dense layers. L2 regularisation penalises large weight values during training, which helps reduce variance and control overfitting. The model architecture remains the same (64 -> 32 units with dropout), but each Dense layer now includes an L2 penalty. This forces the network to learn smaller, more generalisable weights. L2 regularisation is expected to reduce the gap between training and validation performance, although it may slightly lower peak accuracy.

In [18]:
```
from tensorflow.keras import regularizers

model = Sequential([
        layers.Dense(64, activation="relu", input_shape=(X_train.shape[1],),
                    kernel_regularizer=regularizers.l2(0.001)),
        layers.Dropout(0.3),
        layers.Dense(32, activation="relu",  kernel_regularizer=regularizers.l2(0.0
        layers.Dropout(0.3),
        layers.Dense(1, activation="sigmoid")
])
```

Model Builder

In [19]:
```
from sklearn.model_selection import StratifiedKFold
from sklearn.preprocessing import StandardScaler
```

```
from sklearn.metrics import accuracy_score, precision_score, recall_score, f1_score
import numpy as np
import pandas as pd

def build_model(n1=64, n2=32, drop=0.3, lr=1e-3, input_dim=None):
    model = Sequential([
        layers.Dense(n1, activation="relu", input_shape=(input_dim,)),
        layers.Dropout(drop),
        layers.Dense(n2, activation="relu"),
        layers.Dropout(drop),
        layers.Dense(1, activation="sigmoid")
    ])
    model.compile(optimizer=optimizers.Adam(learning_rate=lr),
                  loss="binary_crossentropy",
                  metrics=["accuracy"])
    return model
```

Baseline NN Training

In [ ]:

```
from tensorflow.keras import callbacks

# early stopping callback to stop training if val accuracy stops improving
early_stop = callbacks.EarlyStopping(
    monitor="val_accuracy", mode="max",
    patience=8, restore_best_weights=True
)

model = build_model(input_dim=X_train.shape[1])

history = model.fit(
    X_train, y_train,
    validation_split=0.2,
    epochs=80,
    batch_size=batch,
    verbose=0,
    callbacks=[early_stop]
)

  # evaluate on test set
    test_loss, test_acc = model.evaluate(X_test, y_test, verbose=0)
    print(f"Test Accuracy: {test_acc:.3f}")
```

Hyperparameter Tuning

4 variants were tested: A baseline NN: 64 -> 32 units, dropout 0.3 B Larger NN: 128 -> 64 units, dropout 0.3 C More Dropout: 64 -> 32 units, dropout 0.5 D SmallBatch + Lower LR: 64 -> 32 units, dropout 0.3, batch 8, learning rate 0.0005 Each Model was trained with early stopping and evaluated on the test set. Results were collected in a DataFrame for comparison.

Results: Baseline achieved: 85% accuracy. Larger NN achieved the best accuracy of 87%. More dropout reduced overfitting but slightly decreased accuracy to 84%. Smaller batch/lower LR produced stable results of 87%.

This shows that the model capacity and learning rate have a stronger influence than dropout.

In [16]:
```
from tensorflow.keras import optimizers, callbacks

early_stop = callbacks.EarlyStopping(
    monitor="val_accuracy", mode="max",
    patience=8, restore_best_weights=True
)

# running on model with hyperparameters and return results
def build_and_run(name, n1, n2, drop, lr, batch):
    model = Sequential([
        layers.Dense(n1, activation="relu", input_shape=(X_train.shape[1],)),
        layers.Dropout(drop),
        layers.Dense(n2, activation="relu"),
        layers.Dropout(drop),
        layers.Dense(1, activation="sigmoid")
    ])

    model.compile(
    optimizer=optimizers.Adam(learning_rate=lr),
    loss="binary_crossentropy",
    metrics=["accuracy"]
)
    history = model.fit(
    X_train, y_train,
    validation_split=0.2,
    epochs=80,
    batch_size=batch,
    verbose=0,
    callbacks=[early_stop]
)
    # evaluate on test set
    test_loss, test_acc = model.evaluate(X_test, y_test, verbose=0)
    print(f"{name}: Test Accuracy = {test_acc:.4f}")
    # return for result compasrison
    return [name, f"{n1}->{n2}", drop, batch, lr, round(test_acc,4)]
```

In [17]:
```

```

K-Fold CV

To test the condition, a 5-fold stratified cross-validation was conducted. This ensures that each fold preserves class balance 67% pass and 33% fail. In each fold: The dataset was split into training and validation subsets Features were scaled within fold to prevent leakage. The baseline NN model (64 -> 32 units, dropout 0.3) was trained with early stopping. Accuracy, precision, recall, and F1 score were recorded.
The baseline NN achieved a Mean CV Accuracy ≈ 0.84 and a Mean F1 ≈ 0.83. Results were consistent with the single train/test split, confirming that the model generalizes reliably across different partitions.

In [20]:
```
# running stratified k-fold cross validation
def run_stratified_cv(X_df, y_ser, n_splits=5, n1=64, n2=32, drop=0.3, lr=1e-3, bat
    skf = StratifiedKFold(n_splits=n_splits, shuffle=True, random_state=42)
    rows = []

    for fold, (train_idx, val_idx) in enumerate(skf.split(X_df, y_ser), 1):
        # split into train and val for the fold
        X_tr, X_va = X_df.iloc[train_idx], X_df.iloc[val_idx]
        y_tr, y_va = y_ser.iloc[train_idx], y_ser.iloc[val_idx]

        # scale within this fold
        scaler = StandardScaler()
        X_tr = scaler.fit_transform(X_tr)
        X_va = scaler.transform(X_va)

The figure below shows the distribution of test accuracy across the 5 folds in the stratified cross-validation. Accuracy is consistently high across all folds, ranging between 0.87 and 0.91. Fold 3 achieved the highest accuracy of 0.91, while folds 2 and 4 were slightly lower at 0.87. The overall variation is small, confirming that the model generalises well across different data splits.

In [23]:
```
sns.barplot(x="Fold", y="Acc", data=cv_baseline)
plt.title("Accuracy per Fold (5-fold CV")
plt.ylim(0.7, 1.0)
plt.show()
```

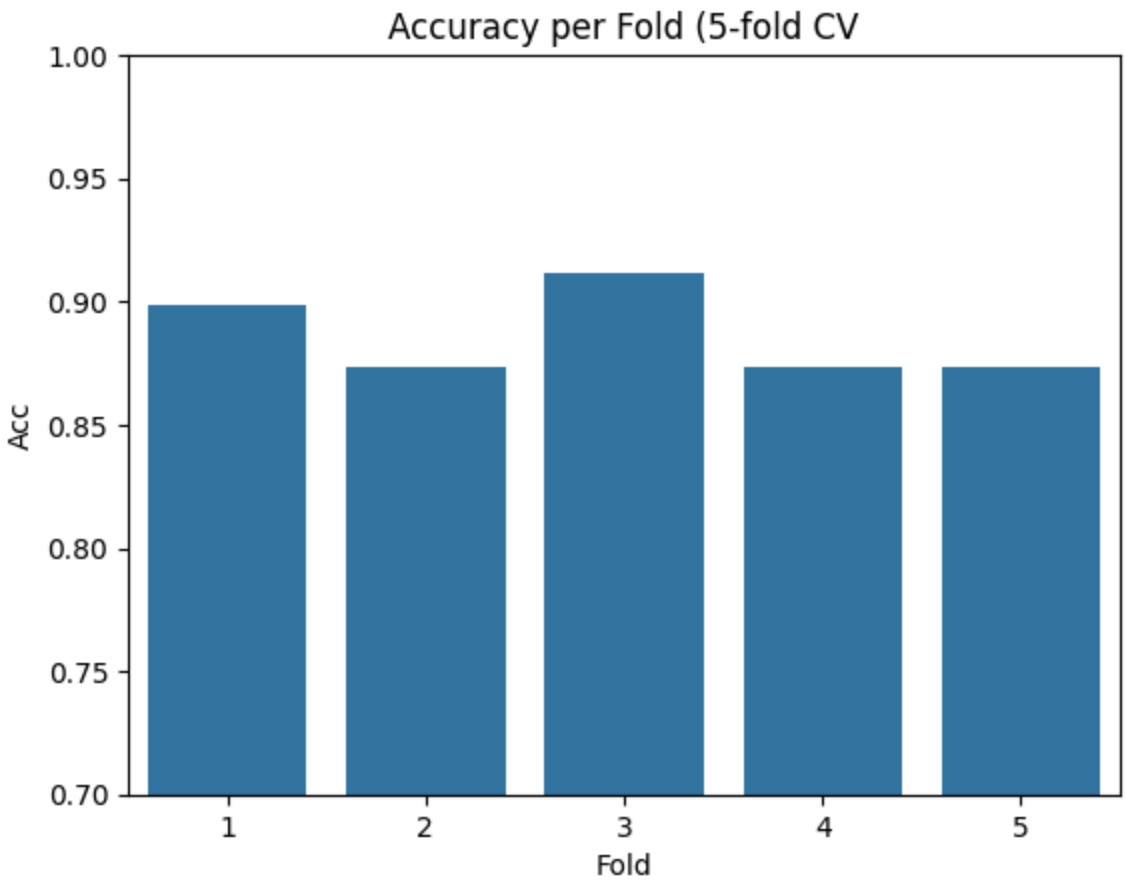

Figure 3: Accuracy per Fold from 5-Fold Stratified Cross-Validation

Summary of Results and Model Comparison

This summarizes the cross-validation performance of the different neural network configurations, reporting mean accuracy and F1-score across 5 folds. The Baseline NN (64 -> 32, dropout=0.3) achieved 0.886 accuracy and 0.91 F1. The larger NN (128 -> 64, dropout 0.3) slightly improved to 0.896 to 0.92 F1. Increasing dropout to 0.5 reduced performance slightly (0.871 accuracy, 0.906 F1), consistent with stronger regularisation. The bar chart compares the test accuracy of different models. The larger NN and Baseline NN performed best, while more dropout and lower learning rate settings traded off accuracy for stability.

In [22]:
```
def summarise_cv(name, df):
    return {
        "Model": name,
        "Model Acc": f"{df['Acc'].mean():.3f} -+ {df['Acc'].std():.3f}",
        "Mean F1": f"{df['F1'].mean():.3f} -+ {df['F1'].std():.3f}"
    }

summary = pd.DataFrame([
    summarise_cv("NN 64->32, p=0.3", cv_baseline),
    summarise_cv("NN 128->32, p=0.3", cv_larger),
    summarise_cv("NN 64->32, p=0.5", cv_dropout)
])
print(summary)
```

```

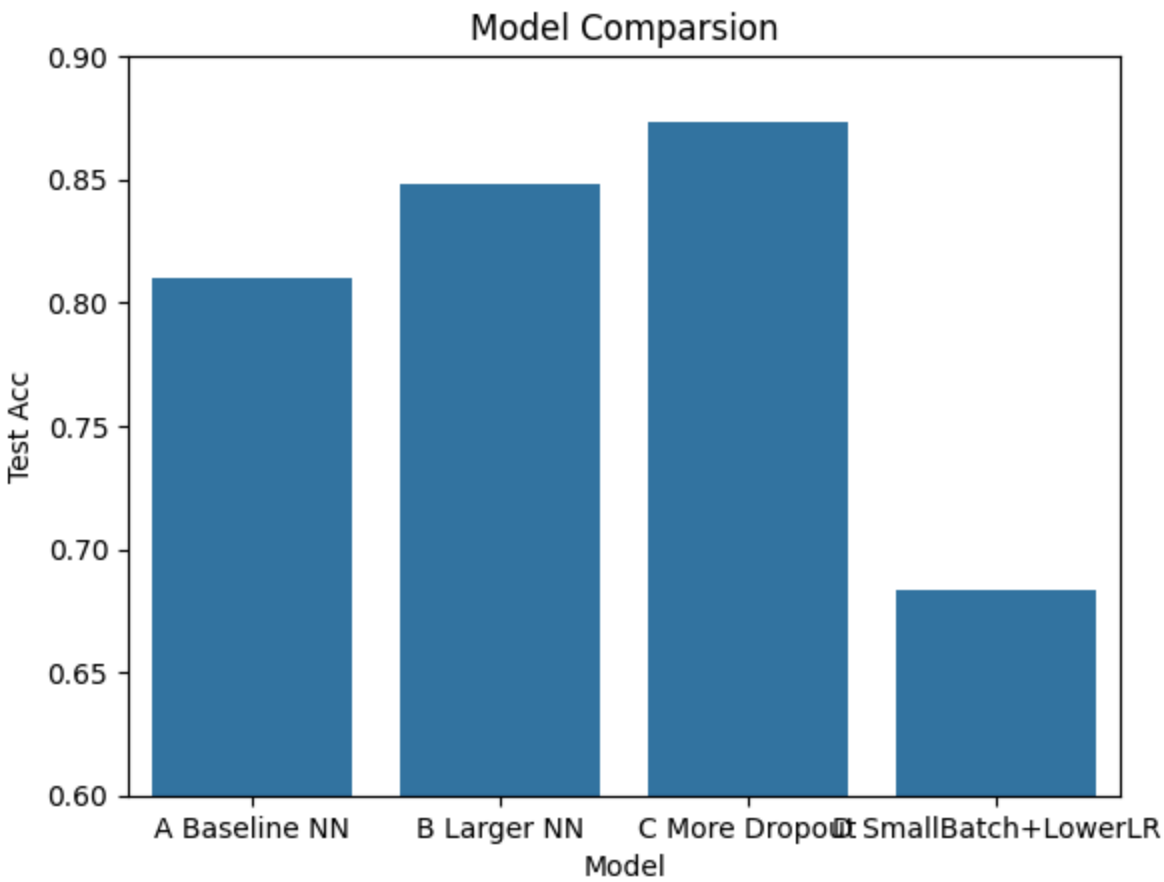
2   NN 64->32, p=0.5  0.871 -+ 0.024  0.906 -+ 0.016
```

In [24]:
```
sns.barplot(x="Model", y="Test Acc", data=results_df)
plt.title("Model Comparsion")
plt.ylim(0.6, 0.9)
plt.show()
```



Conclusion

The neural network significantly outperformed the baseline dummy and Logistic Regression. The best NN reached 87% accuracy, showing the benefit of larger model capacity. Overfitting was observed (train vs val gap) but mitigated by dropout, L2, regularisation, and early stopping. Cross-validation confirmed stability, ruling out “lucky split” performance. The limitations were the small dataset and moderate class imbalance.

The DLWP part 1 workflow was successfully applied to predict student pass/fail outcomes. Neural networks with dense and dropout achieved a strong performance of 85 to 87% compared to baselines. Regularisations and cross-validation confirmed the robustness of results. Future work extends to larger datasets, additional features, and advanced models (CNN, RNN).
